

Introduction to Boosted Trees

Tianqi Chen Oct. 22 2014

Outline

Review of key concepts of supervised learning

Regression Tree and Ensemble (What are we Learning)

Gradient Boosting (How do we Learn)

Summary

Elements in Supervised Learning

- Notations: $x_i \in \mathbf{R}^d$ i-th training example
- **Model**: how to make prediction \hat{y}_i given x_i
 - Linear model: $\hat{y}_i = \sum_j w_j x_{ij}$ (include linear/logistic regression)
 - The prediction score \hat{y}_i can have different interpretations depending on the task
 - Linear regression: \hat{y}_i is the predicted score
 - Logistic regression: $1/(1 + exp(-\hat{y}_i))$ is predicted the probability of the instance being positive
 - Others... for example in ranking \hat{y}_i can be the rank score
- Parameters: the things we need to learn from data
 - Linear model: $\Theta = \{w_j | j = 1, \dots, d\}$

Elements continued: Objective Function

Objective function that is everywhere

$$Obj(\Theta) = L(\Theta) + \Omega(\Theta)$$

Training Loss measures how well model fit on training data

Regularization, measures complexity of model

- Loss on training data: $L = \sum_{i=1}^{n} l(y_i, \hat{y}_i)$
 - Square loss: $l(y_i, \hat{y}_i) = (y_i \hat{y}_i)^2$
 - Logistic loss: $l(y_i, \hat{y}_i) = y_i \ln(1 + e^{-\hat{y}_i}) + (1 y_i) \ln(1 + e^{\hat{y}_i})$
- Regularization: how complicated the model is?
 - L2 norm: $\Omega(w) = \lambda ||w||^2$
 - L1 norm (lasso): $\Omega(w) = \lambda ||w||_1$

Putting known knowledge into context

- Ridge regression: $\sum_{i=1}^{n} (y_i w^T x_i)^2 + \lambda ||w||^2$
 - Linear model, square loss, L2 regularization
- Lasso: $\sum_{i=1}^{n} (y_i w^T x_i)^2 + \lambda ||w||_1$
 - Linear model, square loss, L1 regularization
- Logistic regression:

$$\sum_{i=1}^{n} [y_i \ln(1 + e^{-w^T x_i}) + (1 - y_i) \ln(1 + e^{w^T x_i})] + \lambda ||w||^2$$

- Linear model, logistic loss, L2 regularization
- The conceptual separation between model, parameter, objective also gives you engineering benefits.
 - Think of how you can implement SGD for both ridge regression and logistic regression

Objective and Bias Variance Trade-off

$$Obj(\Theta) = L(\Theta) + \Omega(\Theta)$$

Training Loss measures how well model fit on training data

Regularization, measures complexity of model

- Why do we want to contain two component in the objective?
- Optimizing training loss encourages predictive models
 - Fitting well in training data at least get you close to training data which is hopefully close to the underlying distribution
- Optimizing regularization encourages simple models
 - Simpler models tends to have smaller variance in future predictions, making prediction stable

Outline

Review of key concepts of supervised learning

Regression Tree and Ensemble (What are we Learning)

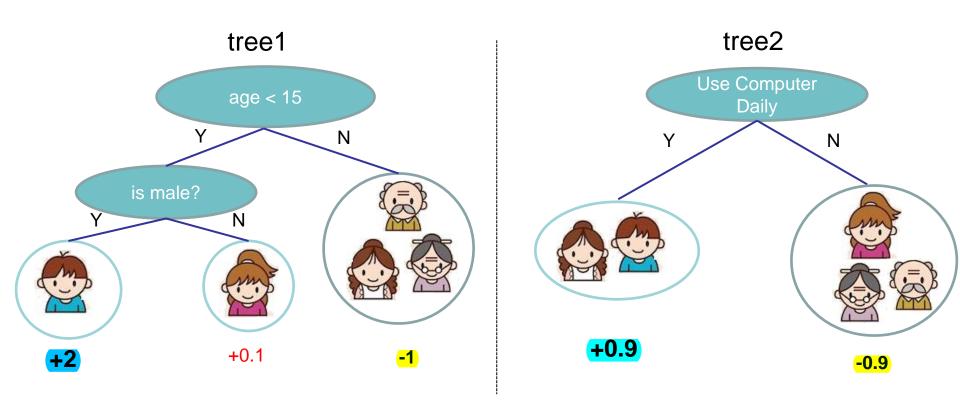

Gradient Boosting (How do we Learn)

Summary

Regression Tree (CART)

- regression tree (also known as classification and regression tree):
 - Decision rules same as in decision tree
 - Contains one score in each leaf value

Regression Tree Ensemble

$$) = 2 + 0.9 = 2.9$$
 f($) = -1 - 0.9 = -1.9$

$$)=-1-0.9=-1.9$$

Prediction of is sum of scores predicted by each of the tree

Tree Ensemble methods

- Very widely used, look for GBM, random forest...
 - Almost half of data mining competition are won by using some variants of tree ensemble methods

 Invariant to scaling of inputs, so you do not need to do careful features normalization.

Learn higher order interaction between features.

可伸缩、可扩展

Can be scalable, and are used in Industry

Put into context: Model and Parameters

Model: assuming we have K trees

$$\hat{y}_i = \sum_{k=1}^K f_k(x_i), \quad f_k \in \mathcal{F}$$

Space of functions containing all Regression trees

Think: regression tree is a function that maps the attributes to the score

- Parameters
 - Including structure of each tree, and the score in the leaf
 - Or simply use function as parameters

$$\Theta = \{f_1, f_2, \cdots, f_K\}$$

• Instead learning weights in \mathbb{R}^d , we are learning functions (trees)

Learning a tree on single variable

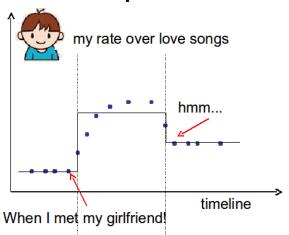

例如:一维特征空间的决策树 学习

- How can we learn functions?
- Define objective (loss, regularization), and optimize it!!
- Example:
 - Consider regression tree on single input t (time)
 - I want to predict whether I like romantic music at time t

The model is regression tree that splits on time

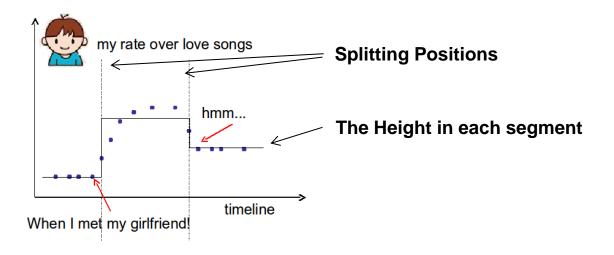

t < 2011/03/01 Y N Equivalently 0.2 1.2

Piecewise step function over time

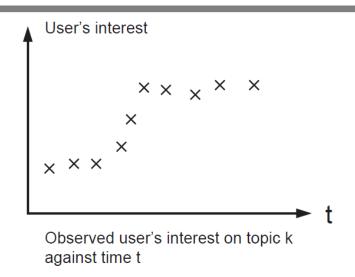

Learning a step function

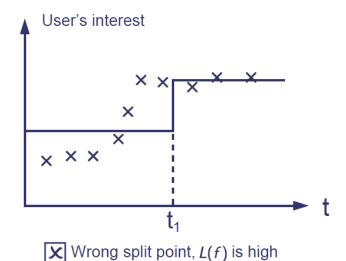

Things we need to learn

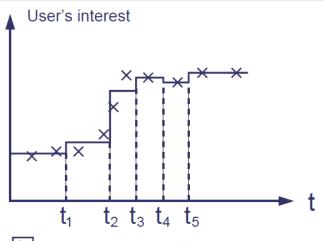

- Objective for single variable regression tree(step functions)
 - Training Loss: How will the function fit on the points?
 - Regularization: How do we define complexity of the function?
 - Number of splitting points, l2 norm of the height in each segment?

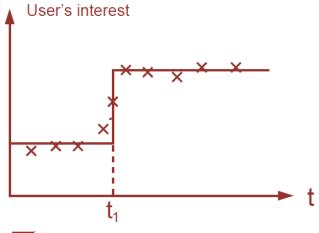

Learning step function (visually)

 \bigcirc Good balance of $\Omega(f)$ and L(f)

Coming back: Objective for Tree Ensemble

Model: assuming we have K trees

$$\hat{y}_i = \sum_{k=1}^K f_k(x_i), \quad f_k \in \mathcal{F}$$

预测模型由K个CART树组成; 预测模型的学习内容就是K个CART树

Objective

$$Obj = \sum_{i=1}^n l(y_i, \hat{y}_i) + \sum_{k=1}^K \Omega(f_k)$$
 Training loss Complexity of the Trees

- Possible ways to define Ω ?
 - Number of nodes in the tree, depth
 - L2 norm of the leaf weights
 - ... detailed later

Objective vs Heuristic

- When you talk about (decision) trees, it is usually heuristics
 - Split by information gain
 - Prune the tree
 - Maximum depth
 - Smooth the leaf values
- Most heuristics maps well to objectives, taking the formal (objective) view let us know what we are learning
 - Information gain -> training loss
 - Pruning -> regularization defined by #nodes
 - Max depth -> constraint on the function space
 - Smoothing leaf values -> L2 regularization on leaf weights

Regression Tree is not just for regression!

- Regression tree ensemble defines how you make the prediction score, it can be used for
 - Classification, Regression, Ranking....
 -
- It all depends on how you define the objective function!
- So far we have learned:
 - Using Square loss $l(y_i, \hat{y}_i) = (y_i \hat{y}_i)^2$
 - Will results in common gradient boosted machine
 - Using Logistic loss $l(y_i, \hat{y}_i) = y_i \ln(1 + e^{-\hat{y}_i}) + (1 y_i) \ln(1 + e^{\hat{y}_i})$
 - Will results in LogitBoost

Outline

Review of key concepts of supervised learning

Regression Tree and Ensemble (What are we Learning)

Gradient Boosting (How do we Learn)

Summary

Take Home Message for this section

- Bias-variance tradeoff is everywhere
- The loss + regularization objective pattern applies for regression tree learning (function learning)

We want predictive and simple functions

- This defines what we want to learn (objective, model).
- But how do we learn it?
 - Next section

So How do we Learn?

- Objective: $\sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{k} \Omega(f_k), f_k \in \mathcal{F}$
- We can not use methods such as SGD, to find f (since they are trees, instead of just numerical vectors)

递增式学习,第t棵树的学习是在

- Solution: Additive Training (Boosting) 前t-1棵树学习的基础上进行的
 - Start from constant prediction, add a new function each time

$$\begin{array}{ll} \hat{y}_{i}^{(0)} &= 0 \\ \hat{y}_{i}^{(1)} &= f_{1}(x_{i}) = \hat{y}_{i}^{(0)} + f_{1}(x_{i}) \\ \hat{y}_{i}^{(2)} &= f_{1}(x_{i}) + f_{2}(x_{i}) = \hat{y}_{i}^{(1)} + f_{2}(x_{i}) \\ & \cdots \\ \hat{y}_{i}^{(t)} &= \sum_{k=1}^{t} f_{k}(x_{i}) = \hat{y}_{i}^{(t-1)} + f_{t}(x_{i}) & \longleftarrow & \text{New function} \\ \nearrow & & & & & & & & & & & & \\ \end{array}$$

Model at training round t Keep functions added in previous round

Additive Training

- How do we decide which f to add?
 - Optimize the objective!!
- The prediction at round t is $\hat{y}_i^{(t)} = \hat{y}_i^{(t-1)} + f_t(x_i)$

This is what we need to decide in round t

$$Obj^{(t)} = \sum_{i=1}^{n} l(y_i, \hat{y}_i^{(t)}) + \sum_{i=1}^{t} \Omega(f_i)$$

$$= \sum_{i=1}^{n} l(y_i, \hat{y}_i^{(t-1)}) + f_t(x_i) + \Omega(f_t) + constant$$

Goal: find f_t to minimize this

Consider square loss

$$Obj^{(t)} = \sum_{i=1}^{n} \left(y_i - (\hat{y}_i^{(t-1)} + f_t(x_i)) \right)^2 + \Omega(f_t) + const$$
$$= \sum_{i=1}^{n} \left[2(\hat{y}_i^{(t-1)} - y_i) f_t(x_i) + f_t(x_i)^2 \right] + \Omega(f_t) + const$$

ft的相关项 ft的无关项

This is usually called residual from previous round

Taylor Expansion Approximation of Loss

- Goal $Obj^{(t)} = \sum_{i=1}^{n} l\left(y_i, \hat{y}_i^{(t-1)} + f_t(x_i)\right) + \Omega(f_t) + constant$
 - Seems still complicated except for the case of square loss
- Take Taylor expansion of the objective
 - Recall $f(x+\Delta x)\simeq f(x)+f'(x)\Delta x+\frac{1}{2}f''(x)\Delta x^2$
 - Define $g_i = \partial_{\hat{y}^{(t-1)}} l(y_i, \hat{y}^{(t-1)}), \quad h_i = \partial_{\hat{y}^{(t-1)}}^2 l(y_i, \hat{y}^{(t-1)})$

$$Obj^{(t)} \simeq \sum_{i=1}^{n} \left[l(y_i, \hat{y}_i^{(t-1)}) + g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i) \right] + \Omega(f_t) + constant$$

这部分与ft无关,可以作为常数项

• If you are not comfortable with this, think of square loss

$$g_i = \partial_{\hat{y}^{(t-1)}} (\hat{y}^{(t-1)} - y_i)^2 = 2(\hat{y}^{(t-1)} - y_i) \quad h_i = \partial_{\hat{y}^{(t-1)}}^2 (y_i - \hat{y}^{(t-1)})^2 = 2$$

Compare what we get to previous slide

Our New Goal

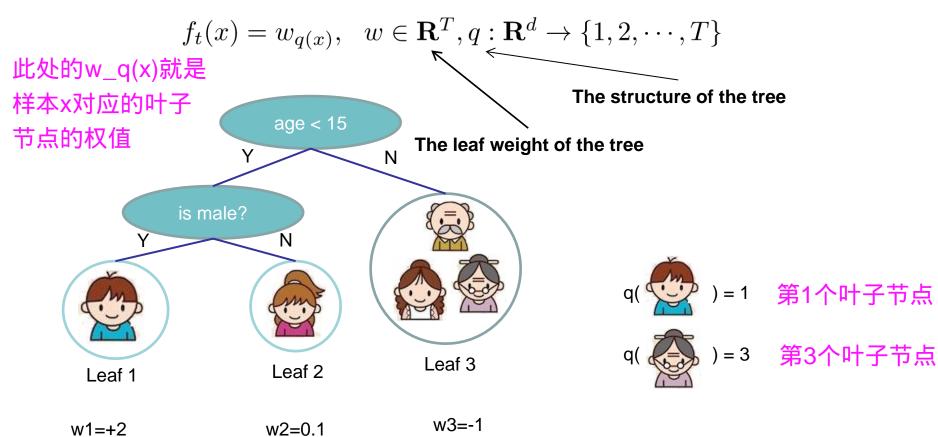

Objective, with constants removed

$$\sum_{i=1}^{n} \left[g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i) \right] + \Omega(f_t)$$

- where $g_i = \partial_{\hat{y}^{(t-1)}} l(y_i, \hat{y}^{(t-1)}), \quad h_i = \partial^2_{\hat{y}^{(t-1)}} l(y_i, \hat{y}^{(t-1)})$
- Why spending s much efforts to derive the objective, why not just grow trees ...
 - Theoretical benefit: know what we are learning, convergence
 - Engineering benefit, recall the elements of supervised learning
 - g_i and h_i comes from definition of loss function
 - ullet The learning of function only depend on the objective via g_i and h_i
 - Think of how you can separate modules of your code when you are asked to implement boosted tree for both square loss and logistic loss

Refine the definition of tree

 We define tree by a vector of scores in leafs, and a leaf index mapping function that maps an instance to a leaf

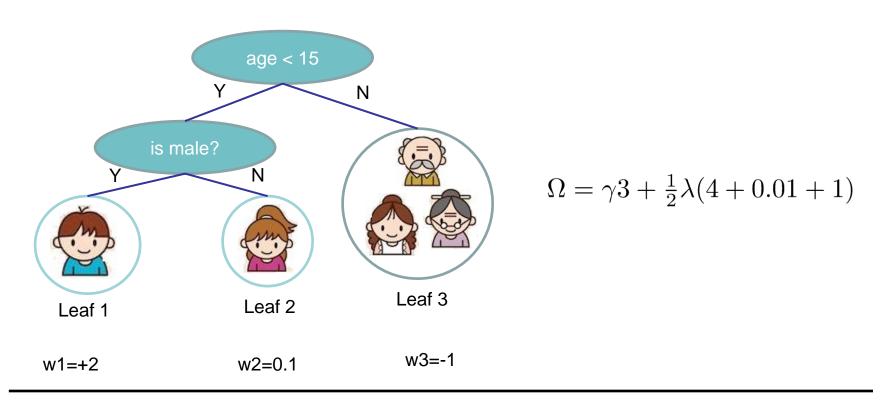

Define Complexity of a Tree (cont')

Define complexity as (this is not the only possible definition)

$$\Omega(f_t) = \gamma T + \frac{1}{2}\lambda \sum_{j=1}^{T} w_j^2$$

Number of leaves

L2 norm of leaf scores

Revisit the Objectives

- Regroup the objective by each leaf

$$Obj^{(t)} \simeq \sum_{i=1}^{n} \left[g_{i} f_{t}(x_{i}) + \frac{1}{2} h_{i} f_{t}^{2}(x_{i}) \right] + \Omega(f_{t})$$

$$= \sum_{i=1}^{n} \left[g_{i} w_{q(x_{i})} + \frac{1}{2} h_{i} w_{q(x_{i})}^{2} \right] + \gamma T + \lambda \frac{1}{2} \sum_{j=1}^{T} w_{j}^{2}$$

$$= \sum_{j=1}^{T} \left[(\sum_{i \in I_{j}} g_{i}) w_{j} + \frac{1}{2} (\sum_{i \in I_{j}} h_{i} + \lambda) w_{j}^{2} \right] + \gamma T$$

This is sum of T independent quadratic functions

The Structure Score

Two facts about single variable quadratic function

$$argmin_x Gx + \frac{1}{2}Hx^2 = -\frac{G}{H}, \ H > 0$$
 $\min_x Gx + \frac{1}{2}Hx^2 = -\frac{1}{2}\frac{G^2}{H}$

• Let us define $G_j = \sum_{i \in I_j} g_i \ H_j = \sum_{i \in I_j} h_i$

$$Obj^{(t)} = \sum_{j=1}^{T} \left[(\sum_{i \in I_j} g_i) w_j + \frac{1}{2} (\sum_{i \in I_j} h_i + \lambda) w_j^2 \right] + \gamma T$$

= $\sum_{j=1}^{T} \left[G_j w_j + \frac{1}{2} (H_j + \lambda) w_j^2 \right] + \gamma T$

• Assume the structure of tree (q(x)) is fixed, the optimal weight in each leaf, and the resulting objective value are

$$w_j^* = -\frac{G_j}{H_j + \lambda} \quad Obj = -\frac{1}{2} \sum_{j=1}^T \frac{G_j^2}{H_j + \lambda} + \gamma T$$

This measures how good a tree structure is!

The Structure Score Calculation

Instance index

gradient statistics

1

g1, h1

2

g2, h2

3

g3, h3

4

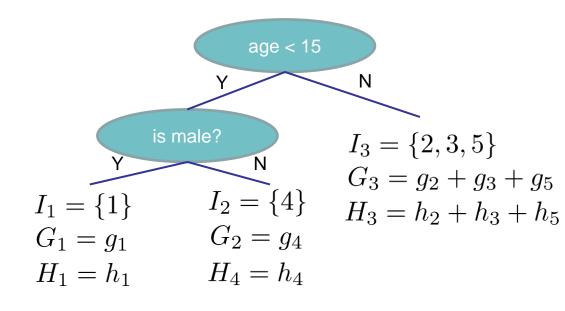

g4, h4

5

g5, h5

$$Obj = -\sum_{j} \frac{G_{j}^{2}}{H_{j} + \lambda} + 3\gamma$$

The smaller the score is, the better the structure is

Searching Algorithm for Single Tree

- Enumerate the possible tree structures q
- Calculate the structure score for the q, using the scoring eq.

$$Obj = -\frac{1}{2} \sum_{j=1}^{T} \frac{G_j^2}{H_j + \lambda} + \gamma T$$

Find the best tree structure, and use the optimal leaf weight

$$w_j^* = -\frac{G_j}{H_j + \lambda}$$

But... there can be infinite possible tree structures..

Greedy Learning of the Tree

- In practice, we grow the tree greedily
 - Start from tree with depth 0
 - For each leaf node of the tree, try to add a split. The change of objective after adding the split is

 The complexity cost by

introducing additional leaf

Remaining question: how do we find the best split?

Efficient Finding of the Best Split

• What is the gain of a split rule $x_j < a$? Say x_j is age

All we need is sum of g and h in each side, and calculate

$$Gain = \frac{G_L^2}{H_L + \lambda} + \frac{G_R^2}{H_R + \lambda} - \frac{(G_L + G_R)^2}{H_L + H_R + \lambda} - \gamma$$

 Left to right linear scan over sorted instance is enough to decide the best split along the feature

An Algorithm for Split Finding

- For each node, enumerate over all features
 - For each feature, sorted the instances by feature value
 - Use a linear scan to decide the best split along that feature
 - Take the best split solution along all the features

- Time Complexity growing a tree of depth K
 - It is O(n d K log n): or each level, need O(n log n) time to sort
 There are d features, and we need to do it for K level
 - This can be further optimized (e.g. use approximation or caching the sorted features)
 - Can scale to very large dataset

What about Categorical Variables?

- Some tree learning algorithm handles categorical variable and continuous variable separately
 - We can easily use the scoring formula we derived to score split based on categorical variables.
- Actually it is not necessary to handle categorical separately.
 - We can encode the categorical variables into numerical vector using one-hot encoding. Allocate a #categorical length vector

$$z_j = \begin{cases} 1 & \text{if } x \text{ is in category } j \\ 0 & otherwise \end{cases}$$

 The vector will be sparse if there are lots of categories, the learning algorithm is preferred to handle sparse data

Pruning and Regularization 分裂后的目标函数值-分裂前的目标函数值=?

Recall the gain of split, it can be negative!

$$Gain = \frac{G_L^2}{H_L + \lambda} + \frac{G_R^2}{H_R + \lambda} - \frac{(G_L + G_R)^2}{H_L + H_R + \lambda} - \gamma$$

- When the training loss reduction is smaller than regularization
- Trade-off between simplicity and predictivness
- Pre-stopping
 - Stop split if the best split have negative gain
 - But maybe a split can benefit future splits...
- Post-Prunning
 - Grow a tree to maximum depth, recursively prune all the leaf splits with negative gain

Recap: Boosted Tree Algorithm

- Add a new tree in each iteration
- Beginning of each iteration, calculate

$$g_i = \partial_{\hat{y}^{(t-1)}} l(y_i, \hat{y}^{(t-1)}), \quad h_i = \partial_{\hat{y}^{(t-1)}}^2 l(y_i, \hat{y}^{(t-1)})$$

• Use the statistics to greedily grow a tree $f_t(x)$

$$Obj = -\frac{1}{2} \sum_{j=1}^{T} \frac{G_j^2}{H_j + \lambda} + \gamma T$$

- Add $f_t(x)$ to the model $\hat{y}_i^{(t)} = \hat{y}_i^{(t-1)} + f_t(x_i)$
 - Usually, instead we do $y^{(t)} = y^{(t-1)} + \epsilon f_t(x_i)$
 - ϵ is called step-size or shrinkage, usually set around 0.1
 - This means we do not do full optimization in each step and reserve chance for future rounds, it helps prevent overfitting

Outline

Review of key concepts of supervised learning

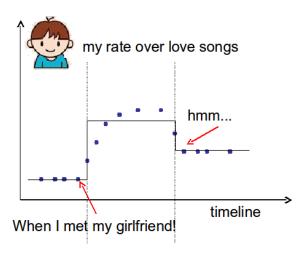

Regression Tree and Ensemble (What are we Learning)

Gradient Boosting (How do we Learn)

Summary

Questions to check if you really get it

- How can we build a boosted tree classifier to do weighted regression problem, such that each instance have a importance weight?
- Back to the time series problem, if I want to learn step functions over time. Is there other ways to learn the time splits, other than the top down split approach?

Questions to check if you really get it

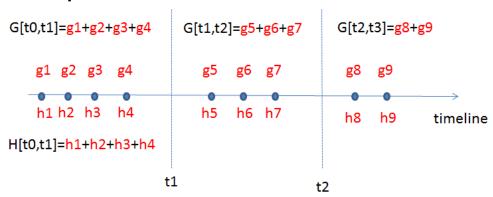

- How can we build a boosted tree classifier to do weighted regression problem, such that each instance have a importance weight?
 - Define objective, calculate g_i, h_i , feed it to the old tree learning algorithm we have for un-weighted version

$$l(y_i, \hat{y}_i) = \frac{1}{2}a_i(\hat{y}_i - y_i)^2$$
 $g_i = a_i(\hat{y}_i - y_i)$ $h_i = a_i$

 Again think of separation of model and objective, how does the theory can help better organizing the machine learning toolkit

Questions to check if you really get it

Time series problem

All that is important is the structure score of the splits

$$Obj = -\frac{1}{2} \sum_{j=1}^{T} \frac{G_j^2}{H_j + \lambda} + \gamma T$$

- Top-down greedy, same as trees
- Bottom-up greedy, start from individual points as each group, greedily merge neighbors
- Dynamic programming, can find optimal solution for this case

Summary

- The separation between model, objective, parameters can be helpful for us to understand and customize learning models
- The bias-variance trade-off applies everywhere, including learning in functional space

$$Obj(\Theta) = L(\Theta) + \Omega(\Theta)$$

We can be formal about what we learn and how we learn.
 Clear understanding of theory can be used to guide cleaner implementation.
